1. (currently amended) A communication link for use in a data processing system, comprising:

a receive interface to receive and convert the voltage levels of a test signal transmitted over a communication channel, where the test signal carries a clock signal and a test data signal;

a clock/data recovery (CDR) circuit coupled to the receive interface and enabled to extract the clock signal and the test data signal from the received signal; and

a debug unit configured to determine a bit error rate (BER) of the test data signal and further configured to determine at least one jitter characteristic of the communication link, wherein the debug unit further includes a test advisor configured to detect a communication problem based upon the BER and the at least one jitter characteristic and to output a first recommendation regarding [[a]] correction of the communication problem, based on in response to determining a first combination of the BER and the at least one jitter characteristic and further configured to output a different second recommendation regarding correction of the communication problem in response to determining a different second combination of the BER and the at least one jitter characteristic.
